(57) **ABSTRACT**

A fish pen (100) includes an elongate spar buoy (110) and an optional reserve buoyancy buoy (120) disposed over a top end of the spar buoy. One or more rim assemblies (130, 140) are attached to the spar buoy with tension members (150, 152, 154). An adjustable upper connection plate (114) on the spar buoy provides a means for tensioning the tension members. A docking station (190) and portal (185) provide easy access to the fish pen. A deployable panel system (180, 182) allows for crowding fish into a smaller portion of the pen. The panel system may be nonporous and include additional panels (184) such that a portion of the pen can be substantially isolated.

CENTER SPAR FISH PEN**CROSS-REFERENCES TO RELATED APPLICATIONS**

This application is a continuation of application Ser. No. 13/338,501, filed Dec. 28, 2011, which claims the benefit of Provisional Application No. 61/428,095, filed Dec. 29, 2010, the disclosures of said applications are hereby expressly incorporated by reference.

BACKGROUND

The seas and other natural water reservoirs have provided an abundant and stable supply of sustenance for millennia. In recent years, however, over-fishing, inefficient harvesting practices, and environmental stressors have resulted in the depletion or decline of certain fish populations in many regions. At the same time, an increasing human population, increasing standards of living, and an increasing awareness of the health benefits of seafood have increased the demand for fish and fish product.

Advances in aquaculture in general and fish farming in particular, and improvements in technology have recently been applied to meet world demand for fish product efficiently and at lower costs. Developments in fish farming also reduce the risks associated with over-fishing existing fish populations. In particular, off-shore cultivation systems employing fish cages or fish pens have found some success. Large, submersible fish pens suitable for aquaculture applications are known in the art to aid in the efficient and bio-responsible cultivation of food sources. Fish pens are placed in a natural body of water, such as a lake, river, or ocean, and stocked with young fish or fry, and the fish are typically fed and maintained until they reach maturity. The fish pens provide a habitat and protection for the fish. Fish pens may be used for freshwater or for saltwater aquaculture.

Some conventional fish farming systems provide a pen that is anchored to the ocean floor. In one embodiment, the pen includes four spar buoys with damper plates coupled to the bottom that dampen the buoy motion caused by wave action. The four spar buoys are typically arranged in a rectangular array with a net fastened to the spar buoys to define a box-like enclosure. Anchor lines extend outwardly and downwardly from each spar buoy to support the nets.

While such conventional fish farming pens have significant advantages, they also have limitations. For example, the fish pen is substantially immobile because the enclosed volume is dependent on the spacing of the individual spar buoys.

More recent innovations in fish pens employing a center spar buoy or center cluster of spar buoys are disclosed in U.S. Pat. No. 5,359,962, to Loverich, and in U.S. Pat. No. 5,617,813, to Loverich et al., both of which are hereby incorporated by reference in their entireties. Loverich et al. discloses a mobile pen for growing fish or shellfish having an elongate central vertical spar buoy surrounded by at least one horizontal net-supporting rim assembly with continuous netting extending from an upper end of the spar buoy to the rim assembly and thence to a lower, submerged end of the spar buoy.

However, there remains a need for improvements in fish pen construction. Fish pens are expensive and can be difficult to assemble and install. Access to aquaculture fish pen in situ is challenging due to its off-shore location, netting exterior,

2

and details of construction. It can be difficult to extract fish from the fish pen and to provide treatment to maintain the health of the fish population.

SUMMARY

This summary is provided to introduce a selection of concepts in a simplified form that are further described below in the Detailed Description. This summary is not intended to identify key features of the claimed subject matter, nor is it intended to be used as an aid in determining the scope of the claimed subject matter.

A fish pen for aquaculture includes an elongate center spar buoy with a reserve buoyancy buoy attached to an upper portion. An upper rim assembly and a lower rim assembly are disposed around the center spar, and attached to the spar with a plurality of tension members. A netting assembly includes a floor portion attached to the center spar and the lower ring assembly, a wall portion attached to the upper and lower rim assemblies, and an upper portion attached to the upper rim assembly and the center spar. Interior panels extending from the center spar to the upper and lower rim assemblies define a smaller operable volume within the netting assembly.

In an embodiment the reserve buoyancy buoy slidably engages a top end of the center spar buoy, for example with a center pipe portion. The fish pen may further comprise a portal door assembly providing access to the enclosed volume, and including upright trough retainers on either side of the portal.

In an embodiment, the fish pen includes a docking station including an upright fender member attached to the upper rim assembly. The fender member may be formed of a steel core covered with a hardened rubber outer covering, and include an inwardly curved lower portion. In an embodiment the docking station further includes a work platform, with a hand-rail system. In an embodiment the upper rim further includes a rim flange member having a cleat assembly to facilitate securing a watercraft to the fish pen.

In an embodiment, the netting assembly is attached to a fixed netting connector plate the center spar buoy, and the netting assembly does not directly engage the tension members.

In an embodiment, one or more of the interior panels are deployable and/or movable within the volume defined by the netting assembly. In an embodiment the interior panels are nonporous. In an embodiment an additional nonporous panels is provided along the netting assembly between the first and second interior panels.

A fish pen is disclosed having an elongate spar buoy, a reserve buoyancy buoy attached to a top end of the spar buoy, upper and lower rim assemblies attached to the spar buoy with a plurality of tension members, a netting assembly attached to the spar buoy and the upper and lower rim assemblies to define an enclosed volume, and first and second interior panels disposed radially from the center spar to the netting assembly perimeter, wherein the outer edge of the second interior panel is pivotable.

DESCRIPTION OF THE DRAWINGS

The foregoing aspects and many of the attendant advantages of this invention will become more readily appreciated as the same become better understood by reference to the following detailed description, when taken in conjunction with the accompanying drawings, wherein:

FIG. 1 is an environmental view showing a center spar fish pen in accordance with the present invention with a live fish

3

carrier docked on one side of the pen and a fish transport container positioned on an opposite side;

FIG. 2 is a front view of the center spar fish pen shown in FIG. 1 shown in isolation;

FIG. 3A is a detail view showing the lower spoke-line connection plate attached to the center spar of the fish pen shown in FIG. 1;

FIG. 3B is a detail view showing one of the upper rim flange assemblies of the fish pen shown in FIG. 1;

FIG. 3C is a detail view showing the upper spoke-line connection plate and the top net connection plate attached to the spar buoy of the fish pen shown in FIG. 1;

FIG. 4 is a detail cross-section view showing the lifejacket buoy disposed on the spar buoy of the fish pen shown in FIG. 1;

FIG. 5 is a detail view showing the netting assembly connection to one of the upper rim flange assemblies of the fish pen shown in FIG. 1;

FIG. 6 is a detail view showing the internal wall system of the fish pen shown in FIG. 1; and

FIG. 7 is a detail view showing a docking station for the fish pen shown in FIG. 1.

DETAILED DESCRIPTION

A currently preferred embodiment of a fish pen **100** in accordance with the present invention will now be described with reference to the figures, wherein like numbers indicate like parts.

FIG. 1 shows an environmental view of the fish pen **100** shown with a ship **80** docked on one side of the fish pen **100**, and a transfer pen **82** moored near the fish pen **100** opposite the ship **80**. The ship **80** may be, for example, a live fish carrier (sometimes referred to as a wellboat) for transporting and transferring immature fish to the fish pen **100**. The transfer pen **82** may be connected to the fish pen **100** through a transfer tunnel **102** (FIG. 2) to permit the transfer of fish between the fish pen **100** to the transfer pen **82**. In an exemplary system, fry or very immature fish are retained in the transfer pen **82** until they have matured sufficiently to be transferred to the fish pen **100**. In another exemplary embodiment, fish ready for market are transferred from the fish pen **100** to the transfer pen **82** and transported therein to a processing station.

Refer also to FIG. 2 which shows a front view of the fish pen **100** in isolation. The fish pen **100** includes an elongate center spar buoy **110**, which is configured to be oriented approximately vertically in the body of water. In an exemplary embodiment the center spar buoy **110** is approximately 32 meters long, and slightly less than 1 meter in diameter. A reserve buoyancy buoy or lifejacket buoy **120** is attached over a top portion of the center spar buoy **110**.

A lower rim assembly **130** is disposed in a lower position about the center spar buoy **110**. The lower rim assembly **130** in the present embodiment comprises eight steel tubular segments **131** arranged to form a generally octagonal rim assembly **130** disposed in a plane perpendicular to the center spar buoy **110**. The lower rim assembly **130** is preferably configured to be negatively or neutrally buoyant. For example, the lower rim assembly **130** may be filled with water.

An upper rim assembly **140** is disposed in an upper position about the center spar buoy **110**, generally parallel to the lower rim assembly **130**. The upper rim assembly **140** may also comprise eight steel tubular segments **141** that are arranged to form a generally octagonal upper rim assembly **140**. The upper rim assembly **140** is configured to be positively buoyant. For example, the upper rim assembly **140** may be filled with air or with a buoyant foam material. In the current

4

embodiment, the upper rim tubular segments **141** are larger in diameter than the lower tubular segments **131** to provide a desired design buoyancy. In the exemplary embodiment, the lower rim assembly **130** and the upper rim assembly **140** are otherwise approximately equal in size and shape. For example, in an exemplary embodiment the rim assemblies **130**, **140** have a transverse dimension of approximately 27 meters.

Although the preferred embodiment is disclosed, the present invention contemplates fish pens larger or smaller than the disclosed embodiment. For example, the fish pen **100** may be readily scaled to different sizes, and/or with differing aspect ratios, to accommodate the needs of particular applications. It is also contemplated that upper and lower rim assemblies may be constructed with more or fewer segments, including rim assemblies that are circular, oval, or the like. A fish pen, in accordance with the present invention, may include more than two rim assemblies, and/or rim assemblies formed from other materials including flexible materials that are pressurized to maintain a desired shape.

The lower rim assembly **130** includes a plurality of flange assemblies **132**. In a current embodiment, the lower tubular segments **131** each include end flange plates that engage corresponding flange plates on adjacent tubular segments **131** to join the segments and define the flange assemblies **132**. The upper rim assembly **140** similarly includes a plurality of spaced apart transverse flange assemblies **142**.

The center spar buoy **110** and upper and lower rim assemblies **140**, **130** are formed into a lightweight, semi-rigid structure with tension members. A set of first tension members **150** each extend from a lower spoke-line connection plate **112** attached to a lower portion of the center spar buoy **110** to a corresponding lower rim flange assembly **132**. As seen most clearly in FIG. 3A, the first tension members **150** each have a connector **151** on one end that releasably engages the lower spoke-line connection plate **112**. A connector (not shown) on the opposite end releasably engages the corresponding lower rim flange assembly **132**.

A set of second tension members **152** each extend from a lower rim flange assembly **132** to a corresponding upper rim flange assembly **142**. In the current embodiment, the second tension members **152** each have a connector on one end (not shown) that releasably engages a lower rim flange assembly **132**, and a connector **153** on the opposite end that releasably engages an upper rim flange assembly **142** (FIG. 3B).

A set of third tension members **154** each extend from an upper rim flange assembly **142** to an upper spoke-line connection plate **114** disposed about an upper portion of the center spar buoy **110**. In the current embodiment, the third tension members **154** each have a connector **155** on one end that releasably engages the associated upper rim flange **142**, and a connector **155** on the opposite end that releasably engages the upper spoke-line connection plate **114** (FIG. 3C).

When the tension members **150**, **152**, **154** are maintained in relatively high tension, the fish pen **100** will substantially comprise a semi-rigid structure maintaining the desired shape while maintaining some desirable flexibility to safely accommodate stressors, for example rogue waves, storm surges, and the like.

Preferably a fourth set of diagonal tension members **156** extend diagonally from the lower rim flange assemblies **132** to the diagonally disposed upper rim flange assemblies **142** to form a W or X truss structure, as seen most readily in FIG. 2. The diagonal tension members **156** reduce or eliminate relative rotational motion between the lower rim assembly **130** and the upper rim assembly **140** providing a desirably more stable geometry.

A unique aspect of the disclosed fish pen **100** is the capability of mooring the fish pen such that the entire net pen will orient in a downstream position relative to the prevailing underwater current direction by securing the mooring line to a single lower rim flange assembly **132**. In particular, the edge of the fish pen **100** opposite the single-point anchor connection will orient furthest downstream (i.e., furthest away from the anchor). A major benefit of this aspect is that ectoparasite eggs will tend to accumulate only on the downstream net panel, and the hatch from these ectoparasite will tend to drift downstream from the net pen (as opposed to drifting into the growing volume of the net pen). In a currently preferred embodiment a mooring line or hawser **133** extends from one of the lower rim flange assemblies **132**, to a fixed object or anchor (not shown), to anchor the fish pen **100** at a desired location. Therefore, if the fish pen **100** is anchored in a body of water having a changing flow stream direction (for example, in a tidal region), the fish pen **100** will re-orient itself such that the same side is disposed in a downstream direction.

FIG. 3A shows a detail view of the lower spoke-line connection plate **112** fixedly attached to a bottom portion of the center spar buoy **110**. Eight cheek plates **117** (six visible) are configured to retain the connectors **151** on the distal ends of the first tension members **150**.

FIG. 3B is a detail view showing one of the upper rim flange assemblies **142** from the upper rim assembly **140**. In a preferred embodiment, a mooring cleat **144** is also provided on one or more of the upper rim flange assemblies **142**, to facilitate watercraft, such as supply ships, maintenance craft, and the like, to dock with the fish pen **100**.

FIG. 3C is a detail view showing the upper spoke-line connection plate **114** adjustably attached to a top portion of the center spar buoy **110**. Four longitudinal adjustment bars **118** having a plurality of attachment apertures are fixedly attached to the center spar buoy **110** and positioned to engage the upper spoke-line connection plate **114**. The upper spoke-line connection plate **114** has a circular center aperture that is slightly larger than the diameter of the upper portion of the center spar buoy **110** with radial cutouts that accommodate the adjustment bars **118** such that the connection plate **114** can move longitudinally along the spar buoy **110**. The connection plate **114** includes four sets of cheek plate assemblies **115**, each positioned to slidably engage one of the adjustment bars **118**, and having locking apertures, such that a bolt or other member can be selectively inserted through the locking apertures and the attachment apertures to fix the connection plate **114** at a desired longitudinal location. Roller assemblies **113** are mounted to the connection plate **114** and engage the center spar buoy **110**, to facilitate adjustment of the connection plate **114**.

Therefore, to assemble the center spar buoy **110** and upper and lower rim assemblies **130**, **140**, after attaching the three sets of tension members **150**, **152**, **154**, the upper spoke-line connection plate **114** is pulled upwardly along the center spar buoy **110** with two or more winches to achieve a desired tension. Locking members are inserted through the cheek plates **115** and adjustment bars **118** to lock the upper spoke-line connection plate **114** at the desired position. Advantageously, the disclosed embodiment does not require workers to access the bottom of the center spar buoy during the tensioning step.

FIG. 4 is a detail cross-section view showing a top portion of the fish pen **100** including a novel reserve buoyancy, or lifejacket, buoy **120** that supports various support equipment **129**. The reserve buoyancy buoy **120** in this embodiment comprises an inner pipe **121** that is sized to be slidably attached over a top end of the center spar buoy **110**, and a

foam outer body **122** disposed around the inner pipe **121**. Optionally, an annular retaining plate **123** is fixed to the inner pipe **121** at an intermediate location to further fix the outer body **122** to the inner pipe **121**. The lower end of the inner pipe **121** extends beyond the outer body **122**, and includes a flange portion **124** that engages a corresponding flange portion **119** fixed to the center spar buoy **110**. The flange portions **119**, **124** are operable for securing the reserve buoyancy buoy **120** to the center spar buoy **110**.

In addition to providing reserve buoyancy to stabilize the fish pen **100** even in stormy or large-wave conditions, the reserve buoyancy buoy **120** cooperatively with the center spar buoy **110** provides a platform for support equipment **129**. For example, the support equipment **129** disposed atop the center spar buoy **110** may include a control system, radio and antenna assembly for monitoring the fish pen **100**, a lighting system to increase the visibility of the fish pen at night and/or in adverse weather, a solar cell and battery system, air pump(s) and valve controls to enable raising and lowering the fish pen **100**, and the like. In a current embodiment, the support equipment **129** is mounted on a support plate and truss system directly over the center spar buoy **110**.

Also shown in FIG. 4 are an upper bulkhead plate **125** and a lower bulkhead plate **126** disposed in an upper portion of the center spar buoy **110**. A vent pipe **127** extends between the upper and lower bulkhead plates **125**, **126**. The lower portion of the center spar buoy **110** is tubular with openings on the bottom end. It will be appreciated, therefore, that to increase the buoyancy of the center spar buoy **110** (e.g., to move the fish pen **100** to a raised position), air is pumped through the vent pipe **127** displacing water from the lower portion of the center spar buoy **110**. To decrease the buoyancy of the center spar buoy **110** (e.g., to move the fish pen **100** to a lowered position), a valve on the vent pipe **127** may be opened to allow air in the lower portion of the center spar buoy **110** to escape and to allow water to enter the lower portion of the center spar buoy **110**. In the present embodiment, a plurality of spaced-apart vent pipe support plates **128** is provided to support the vent pipe **127** along its length.

As seen most clearly in FIGS. 1, 2, and 3C, a netting assembly **160** is supported by the center spar buoy **110** and the upper and lower rim assemblies **130**, **140** to define an enclosure for retaining fish. The detail view of FIG. 3C shows a top net connection plate **170** comprising a flange plate portion **172** fixedly attached to the center spar buoy **110**, and an annular bar portion **174** that is fixed to the flange plate portion **172**. An upper end of the netting assembly **160** is lashed or otherwise attached to the annular bar portion **174** (FIG. 2).

FIG. 5 is a detail view showing a representative corner of the upper rim assembly **140** from above, which is similar in relevant aspects to the other corners of the upper and lower rim assemblies **140**, **130**. The tubular segment **141** includes a stand-off bar **145** that is fixed to the tubular segment with stanchions **146**. The netting assembly **160** is attached to the stand-off bars **145** with a cable or lashing assembly **147**.

As seen most clearly in FIGS. 1 and 2, the netting assembly **160** extends generally along the inside perimeter of the upper and lower rim assemblies **140**, **130**. A generally flat portion of the netting assembly **160** forms a floor that engages the center spar buoy **110** with a lower belt **162** (FIG. 2).

A novel aspect of the current fish pen **100** is that the netting assembly **160** is generally independent of the structural tension members **150**, **152**, **154**, **156**. This provides advantages in design and construction because more options are open for the material selection for the netting assembly **160**.

In a current embodiment, the fish pen **100** includes a fish crowding and/or partitioning system that permits the user to

confine some or all of the fish to a smaller section of the volume of the fish pen **100**. FIG. 6 is a detail view showing a portion of the fish pen **100** with the netting assembly **160** removed for clarity. A first internal wall **180** extends from the center spar buoy **110** to the upper and lower rim assemblies **140**, **130** with a lower edge along the floor of the netting assembly **160** (not shown). The first internal wall **180** may be deployable, and configured to remain at a fixed position when deployed. A second internal wall **182** also extends from the center spar buoy **100** to the upper and lower rim assemblies **140**, **130**. Therefore, the first and second internal walls delineate a portion of the volume of the fish pen **100**.

The second internal wall **182** is preferably deployable and is configured to be swept circumferentially through the fish pen **100** with the inner edge remaining attached to the center spar buoy **100** and the outer edge movable along the netting assembly **160**. The lower edge of the second internal wall **182** remains disposed generally at or near the floor portion of the netting assembly **160**. The second inner wall **182** may be formed of a netting material to facilitate movement through the water.

In this embodiment, the second internal wall **182** may therefore be initially deployed adjacent the first internal wall **180**, and moved around the center spar buoy to a location, for example, to the location shown in FIG. 6, thereby crowding fish in the fish pen **100** into a small region of the fish pen **100**. This may be useful, for example, for extracting the fish from the fish pen **100** or for confining fish in one section to allow for maintenance on other portions of the fish pen **100**.

It is also contemplated that the first and second inner walls **180**, **182** may be formed from a nonporous material, for example, a plastic sheet or the like. Additionally, a similar nonporous internal wall **184** may be deployed along the vertical wall section of the netting assembly **160** adjacent the first and second inner walls **180**, **182** and a similar nonporous internal floor section (not shown) may be deployed below the region defined by the first and second inner walls **180**, **182**. In this configuration, an enclosed region of the fish pen **100** may be selectively isolated from the surrounding body of water when the fish pen is in the raised position. The second inner wall **182** may be swept through the fish pen **100** pivoting about the center spar buoy **110** to crowd the fish into the defined region. Providing a smaller portion of the fish pen **100** substantially isolated from the surrounding body of water will facilitate, for example, treating the fish population when necessary.

For example, if it becomes necessary or desirable to treat the fish with an antimicrobial treatment, antiparasitic, or the like, the fish pen **100** is moved to a raised position, the nonporous internal walls are deployed, and the second internal wall **182** is swept through the fish pen **100** to isolate the fish. A desired treatment may then be deposited into the isolated portion of water, and after waiting sufficient time, the internal wall portions may be retracted. It is contemplated, for example, that other steps may be desirable, for example providing aeration to the isolated water portion during treatment, providing food, etc.

The fish pen **100** optionally includes one or more docking station **190** (two shown in FIG. 2) that may include entryways into the fish pen **100**. FIG. 7 is a detail view showing a docking station **190** disposed adjacent a closable portal **185**. The portal **185** comprises large openings and one or more rigid framed doors **186** that can be opened to provide access to the interior of the fish pen **100**. For example, the portal may be used to stock the fish pen **100** or to remove fish, or to gain access for monitoring and/or maintenance of the fish pen **100** or fish. Conventional mechanisms for opening, closing, and/

or securing the portal may be used. The portal may further include oppositely disposed fish trough panels or nets **187** that extend upright from the portal **185**. The fish trough nets **187** in this embodiment are generally triangular and are operable to prevent fish from escaping from the portal **185** when the portal is open. Preferably, the fish troughs are removable and/or fold down for securement to the netting assembly **160**.

The docking station **190** includes a plurality of upright fender members **191** fixed to the side of an upper rim segment **141** with a web member **192**. The docking station **190** provides an energy absorbent contact location between a vessel **80** and the fish pen **100**. The upright fender members **191** are preferably modular and attached to the upper rim segment **141** with removable fasteners such that they can be quickly and easily replaced. The upright fender members **191** in a current embodiment are fabricated from steel structural members with a hardened rubber marine grade material outer covering. The fender members **191** preferably extend high enough off the water that the railing of a moored vessel will not catch on the top of the fender member **191** from wave-induced motion. The lower portion of the fender members **191** bends in towards the fish pen **100** to avoid any unintended underwater interaction between the hull and the fender members **191**. Conventional fender buoys **195** may also be provided. The nearby cleats **144** on the upper rim flange assembly **142** may be used to secure the watercraft **80** to the fish pen **100**.

The docking station **190** may further include a work platform **194** with a suitable handrail system **193**, to facilitate operator activities, such as stocking or removing fish, performing maintenance, etc. The work platform **194** is affixed to one or more of the upper rim segments **141** and provides the workers with a safe sturdy location to perform normal farm operations. An optional opening in the handrail system **193** allows for easy access to the rim deck from both the fish pen side and ocean side of the work platform **194**. Preferably the work platform **194** is fabricated from a non-metal material, such as fiberglass, to decrease weight and is porous to allow water to pass through. A non-skid finish is applied to the top side of the platform **194**.

While illustrative embodiments have been illustrated and described, it will be appreciated that various changes can be made therein without departing from the spirit and scope of the invention.

The embodiments of the invention in which an exclusive property or privilege is claimed are defined as follows:

1. A fish pen for aquaculture comprising:

an elongate spar buoy;

a lower connection plate attached to a lower portion of the spar buoy;

an upper connection plate adjustably attached to an upper portion of the spar buoy;

a rim assembly having a plurality of flange members at spaced circumferential positions on the rim assembly;

a plurality of lower cable assemblies, each lower cable assembly having a first end attached to the lower connection plate and a second end attached to one of the plurality of flange members;

a plurality of upper cable assemblies, each upper cable assembly having a first end attached to the upper connection plate and a second end attached to one of the plurality of flange members;

a net assembly enclosing a volume, the net assembly comprising a lower portion having an inner edge that engages the spar buoy, an upper edge that engages the spar buoy at an elevation above the rim assembly, and a middle portion attached to the rim assembly;

- a first interior wall having an inner edge attached to the spar buoy and an outer edge that engages the net assembly;
 a second interior wall having an inner edge attached to the spar buoy and an outer edge that engages the net assembly, wherein the first and second interior walls are configured to cooperatively divide the volume enclosed by the net assembly into a first volume portion and a second volume portion;
 wherein the second interior wall is pivotable about the spar buoy to thereby selectively reduce the first volume portion.
2. The fish pen of claim 1, further comprising a reserve buoyancy buoy disposed over a top end of the elongate spar buoy.
3. The fish pen of claim 2, wherein the reserve buoyancy buoy comprises a center pipe portion that is configured to slidably engage the top end of the elongate spar buoy.
4. The fish pen of claim 2, further comprising a radio and antenna system mounted to the reserve buoyancy buoy.
5. The fish pen of claim 1, wherein the net assembly further comprises a portal comprising a door assembly for providing access to the enclosed volume.
6. The fish pen of claim 5, further comprising a pair of oppositely disposed fish trough retainers disposed on either side of the portal.
7. The fish pen of claim 5, further comprising a docking station comprising an upright fender member that is attached to the rim assembly.
8. The fish pen of claim 7, wherein the upright fender member comprises a steel structural member with a hardened rubber marine grade material outer covering, and further wherein a lower portion of the upright fender member is curved inwardly towards the spar buoy.
9. The fish pen of claim 7, wherein the docking station is disposed adjacent the portal, and further comprises a work platform that is attached to the rim assembly.
10. The fish pen of claim 9, wherein the work platform further comprises a handrail system.
11. The fish pen of claim 7, wherein the plurality of flange members further comprise a cleat assembly configured to facilitate securing a watercraft to the fish pen.
12. The fish pen of claim 1, wherein the elongate spar buoy further comprises a fixed netting connector plate, and wherein the net assembly is attached to the netting connector plate.
13. The fish pen of claim 1, wherein the plurality of upper cable assemblies do not directly engage the net assembly.
14. The fish pen of claim 1, wherein the second interior panel comprises a porous netting material, and further wherein the outer edge of the second interior panel is configured to be moved circumferentially to sweep the second interior panel through a portion of the enclosed volume.
15. The fish pen of claim 1, wherein the first and second interior panels are nonporous, and further comprising a third nonporous interior panel disposed adjacent the netting assembly between the first and second interior panels.
16. A fish pen for aquaculture comprising:
 a spar buoy;
 a reserve buoyancy buoy attached to a top end of the spar buoy;

- an annular rim assembly;
 a plurality of lower cable assemblies having a first end attached to a lower portion of the spar buoy and a second end attached to the annular rim assembly;
 a plurality of upper cable assemblies having a first end attached to the annular rim assembly and a second end attached to a lower portion of the spar buoy;
 a net assembly comprising a first edge attached to the lower portion of the spar buoy, a second edge attached to the upper portion of the spar buoy, and an intermediate portion attached to the annular rim assembly, such that the net assembly encloses a volume disposed radially within the annular rim assembly;
 a first interior panel having an inner edge attached to the spar buoy and an outer edge adjacent the net assembly; and
 a second interior panel having an inner edge attached to the spar buoy and an outer edge adjacent the net assembly; wherein the second panel is pivotable about the spar buoy.
17. The fish pen of claim 16, wherein the reserve buoyancy buoy comprises a center pipe portion that is configured to slidably engage a top end of the spar buoy.
18. The fish pen of claim 16, further comprising a radio and antenna system mounted to the reserve buoyancy buoy.
19. The fish pen of claim 16, wherein the net assembly further comprises a portal comprising an openable door assembly for providing access to the enclosed volume.
20. The fish pen of claim 19, further comprising a pair of oppositely disposed fish trough retainers disposed upright on either side of the portal.
21. The fish pen of claim 19, further comprising a docking station comprising a plurality of upright fender members that are attached to the annular rim assembly.
22. The fish pen of claim 21, wherein the docking station is disposed adjacent the portal, and further comprising a work platform that is attached to the annular rim assembly.
23. A fish pen for aquaculture comprising:
 a spar buoy;
 a reserve buoyancy buoy attached to a top end of the spar buoy;
 an annular rim assembly;
 a plurality of cable assemblies having a lower end attached to the spar buoy, an upper end attached to the spar buoy, and a middle portion attached to the annular rim assembly;
 a net assembly comprising an upper edge attached to the spar buoy, a lower edge attached to the spar buoy, and an intermediate portion attached to the annular rim assembly, such that the net assembly encloses a volume disposed radially within the annular rim assembly;
 a fixed interior panel having an inner edge attached to the spar buoy and an outer edge adjacent the net assembly;
 a pivotable interior panel having an inner edge attached to the spar buoy and an outer edge adjacent the net assembly; and
 a radio and antenna system mounted above the spar buoy.
